Threads are the traditional way of offering concurrency

- the execution of the program is split up into concurrently running tasks;
- such tasks operate on shared memory

Several problems

- race conditions with update loss

T_1 (withdraw(10))	T_2 (withdraw(10))	Balance
if (balance - amount >= 0)		15€
	if (balance - amount >= 0)	15€
	balance -= amount;	5€
balance -= amount;		-5€

- deadlocks

P_1	P_2
lock(A)	lock(B)
lock(B)	lock(A)

Erlang (and also Scala via the Akka library) takes a different approach to concurrency: the Actor Model.

Actor Model Concurrency Overview

Actor Model
Concurrency

Walter Cazzola

Concurrency
shared-state

Erlang
concurrency
spawn
send
receive
scheduling
named actors

References

Each object is an actor.

- it has a mailbox and a Behavior;
- actors communicate through messages buffered in a mailbox.

Computation is data-driven, upon receiving a message an actor

- can send a number of messages to other actors;
- can create a number of actors; and
- can assume a different behavior for dealing with the next message in its mailbox.

Note that,

- all communications are performed asynchronously;
 - the sender does not wait for a message to be received upon sending it;
 - no guarantees about the receiving order but they will eventually be delivered.
- there is no shared state between actors
 - information about internal state are requested/provided by messages;
 - also internal state manipulation happens through messages.
- actors run concurrently and are implemented as lightweight user-space threads

- Three basic elements form the foundation for concurrency
- a built-in function (`spawn()`) to create new actors;
 - an operator (`!`) to send a message to another actor; and
 - a mechanism to pattern-match message from the actor's mailbox.

```

```
a(<0.73.0>) stops
```

self() returns the PID of the process.

Concurrency in Erlang

Sending a Message.

Actor Model
Concurrency
in Erlang

Walter Cazzola

Concurrency
shared-state

Erlang
concurrency
spawn
send
receive
scheduling
named actors

References

Every actor is characterized By:

- an address which identifies the actor and
- a **mailbox** where the delivered messages but not cleared yet are stored;

Messages are sorted on arrival time (**not** on sending time).

To send a message to an actor:

- has to know the address (pid) of the target actor;
- to send its address (pid) to the target with the message if a reply is necessary; and
- to use the send (!) primitive.

$\text{Exp}_1 ! \text{Exp}_2$

- Exp_1 must identify an actor;
- Exp_2 any valid Erlang expression; the result of the send expression is the one of Exp_2 ;
- the sending never fails also when the target actor doesn't exist or is unreachable;
- the sending operation never block the sender.

Concurrency in Erlang

Receiving a Message.

Actor Model
Concurrency
in Erlang

Walter Cazzola

Concurrency
shared-state

Erlang

concurrency

spawn

send

receive

scheduling

named actors

References

The receiving operation uses pattern matching.

```
receive
  Any -> do_something(Any)
end
```

- the actor pick out of the mailbox the oldest message matching Any;
- it is Blocked waiting for a message when the queue is empty.

```
receive
  {Pid, something} -> do_something(Pid)
end
```

- the actor tries to pick out the oldest message that matches {Pid, something};
- if it fails the actor is Blocked waiting for such a message

```
receive
  Pattern1 [when GuardSeq1] -> Body1 ;
  ...
  Patternn [when GuardSeqn] -> Bodyn
[after Exprt -> Bodyt]
end
```

- rules definition and evaluation is quite similar to the functions;
- when no pattern matches the mailbox the actor waits instead of raising an exception;
- to avoid waiting forever the clause **after** can be used, after Expr_t ms the actor is woke up.

Actor Scheduling in Erlang.

Actor Model
Concurrency
in Erlang

Walter Cazzola

Concurrency
shared-state

Erlang
concurrency
spawn
send
receive
scheduling
named actors

References

Actors are not processes and are not dealt by the operating system

- the BEAM uses a preemptive scheduler;
- when an actor run for a too long period of time or when it enters a **receive** statement with no message available, the actor is halted and placed on a scheduling queue;

Actors and the rest of the system

- OS processes and actors have different schedulers and long running Erlang applications do not interfere with the execution of the OS processes (no one will become unresponsive)
- the BEAM supports symmetric multiprocessing (SMP)
 - i.e., it can run processes in parallel on multiple CPUs
 - But it cannot run lightweight processes (actors) in parallel on multiple CPUs.

```

Concurrency in Erlang

Giving a Name to the Actors.

Erlang provides a mechanism to render public the pid of a process to all the other processes.

- **register**(an_atom, Pid)
- **unregister**(an_atom)
- **whereis**(an_atom) -> Pid | **undefined**
- **registered**()

Once registered

- it is possible to send a message to it directly (name!msg).

```
-module(clock).  
-export([start/2, stop/0]).  
  
start(Time, Fun) -> register(clock, spawn(fun() -> tick(Time, Fun) end)).  
stop() -> clock ! stop.  
  
tick(Time, Fun) ->  
    receive  
        stop -> void  
    after  
        Time -> Fun(), tick(Time, Fun)  
    end.
```

```
5> clock:start(5000, fun() -> io:format("TICK ~p-n",[erlang:now()]) end).  
true  
TICK 1320,769016,673190  
TICK 1320,769021,678451  
TICK 1320,769026,679120  
7> clock:stop().  
stop
```
